Summary

This report documents the damage to the Pensacola Beach Gulf Pier, also known as the Casino Beach Fishing Pier, caused by Hurricane Sally on September 16th, 2020. Sally made landfall as a Category 2 Hurricane near Gulf Shores, Alabama. Storm surge reached a height of 5.6 feet in Pensacola which is the third-highest level on record. The Fishing Pier was subjected to high winds and wave impacts which caused extensive damage in several areas. The hydraulic forces from wave action dislodged multiple timber deck blowout panels, damaging the timber deck members and shifting the panels. High winds and wave loading destroyed the timber pedestrian railing along with the attached electrical, lighting and water utilities. In addition, concrete damage to piling, pile caps and beams occurred from water forces, debris impacts and the movement of the pier under lateral loads.

The repairs needed to restore the fishing pier to its pre-storm condition include:

1. Replace all pedestrian railing. The new railing should meet ADAAG guidelines.
2. Replace the missing signage, fishing line receptacles, and viewing telescope attached to railing.
3. Replace the electrical wiring and all pier lights with equivalent turtle friendly led fixtures.
4. Replace the water line.
5. Replace the damaged timber deck sections and adjust the blowout panel spacing to meet gap and dip limits of the ADA Section 303 guidelines.
6. Repair and attach the damaged benches.
7. Replace the flagpole.
8. Replace the entrance gate.
9. Repair concrete spall damage and seal concrete cracks in accordance with current FDOT Specifications for Road and Bridge Construction.

The opinion of probable cost for the repair project is $1.98 million.

Preliminary Engineering Assessment

On September 16th, 2020, Hurricane Sally made landfall as a Category 2 Hurricane near Gulf Shores, Alabama with sustained winds of 105 mph and gusts over 120 mph. The Hurricane caused extensive wind, flooding and storm surge damage in areas of Escambia County Florida. Sally was an extremely slow-moving storm which advanced at 2 mph and made landfall moving at 3 mph. Rainfall amounts in Escambia County from 7 am September 14th through 7am September 17th ranged from 12.74" to 24.88". Storm surge reached a height of 5.6 feet in Pensacola which is the third-highest level on record.

The Pensacola Beach Gulf Pier, also known as the Casino Beach Fishing Pier, was subjected to high winds and wave impacts which caused extensive damage in several areas. The hydraulic forces from wave action dislodged multiple timber deck blowout panels, damaging the timber deck members and shifting the panels. High winds and wave loading destroyed the timber pedestrian railing along with the attached electrical, lighting and water utilities. In addition, concrete damage to piling, pile caps and beams occurred from water forces, debris impacts and the movement of the pier under lateral loads. Mott MacDonald visited the pier on multiple occasions from 10/01/2020 to 12/18/2020 to assess the damage documented in this report. Observations were limited to visual identification above water and does not document damage that may have occurred to piling below the waterline. Plans and a previous comprehensive condition report are not available for the pier. Escambia County indicated that damage from previous storms had been repaired prior to Hurricane Sally. This report identifies damage that was likely caused by Hurricane Sally. Damage identified that was not likely caused by Hurricane Sally was not included in the opinion of probable costs for repairs.

Figure 1 – Pensacola Beach Gulf Pier, 09/14/20

Timber Deck Damage:

Hurricane Sally had a significant storm surge and the hydraulic forces from wave action dislodged multiple timber deck blowout panels. Panels are often subject to the highest uplift forces in locations where waves impact piles and pile caps. The hurricane wave action damaged the timber deck through direct impact, impact between items as panels were moved, and by shifting the panels that were not completely dislodged but allowed to move laterally after adjacent panels are blown out. The existing timber deck members also show signs of deterioration that are not related to the hurricane, but the opinion of probable repair costs does not include repairs for this deterioration. Figures 2 through 4 show the dislodged timber deck blowout panels adjacent to bents following the hurricane.

Without additional repairs, replacing blown out panels following a hurricane will not restore the deck to its pre-storm condition. Damaged or warped timbers result in a deck condition with gaps and dips that exceed the Americans with Disabilities Act Guidelines (ADA). ADA Section 302.3 limits the openings between deck members or timber gaps to 0.5” maximum. ADA Section 303.3 requires that changes in level between 0.25” and 0.5” high be beveled with a slope not steeper than 1:2. ADA Section 303.4 requires that changes in level greater than 0.5” high be ramped. Replacement of blown out panels requires replacement of any warped or damaged timbers, repairing concrete spalls, adjusting the spacing of all panels in the span and beveling edges to produce a deck surface that meets ADA Section 303 guidelines. Figures 5 and 6 show typical gaps and dips between blowout panels that exceed 0.5” and do not meet ADA guidelines.

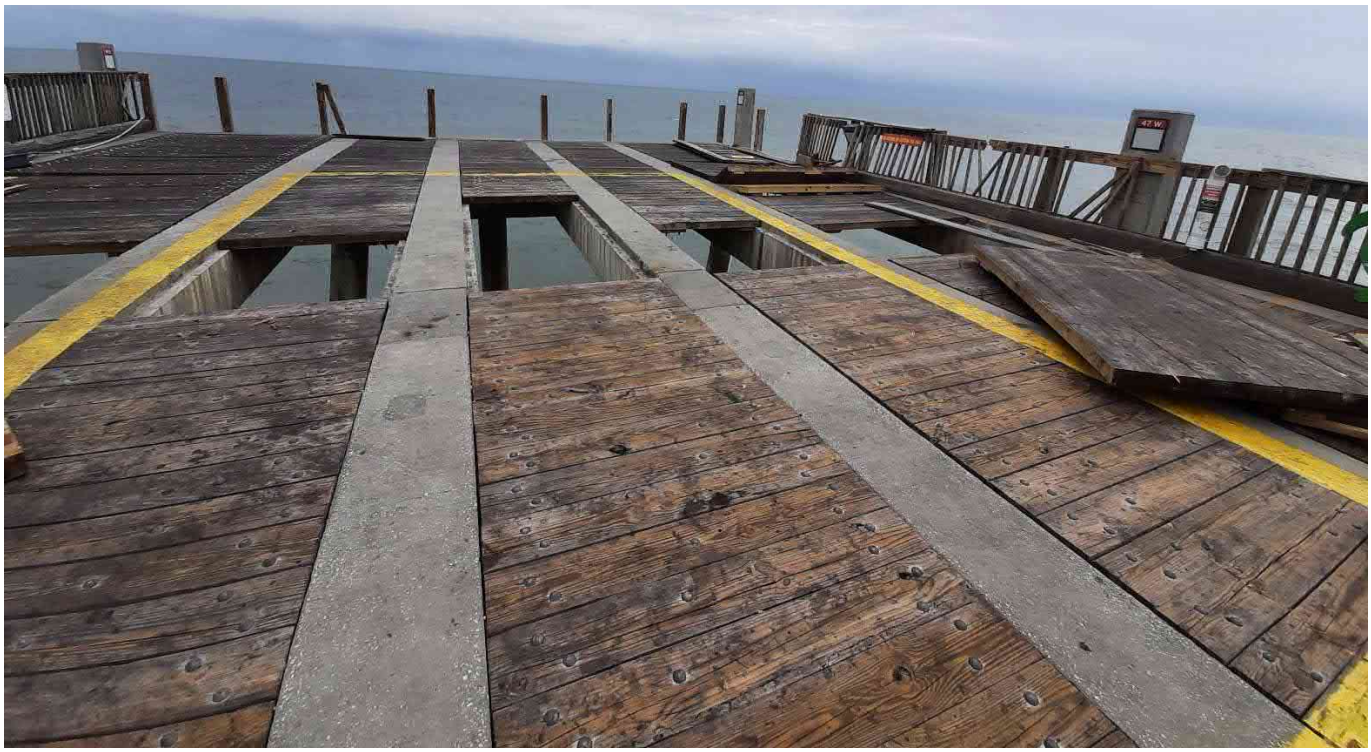

Figure 2 – Timber Deck Blowout Panels adjacent to Bent 47.

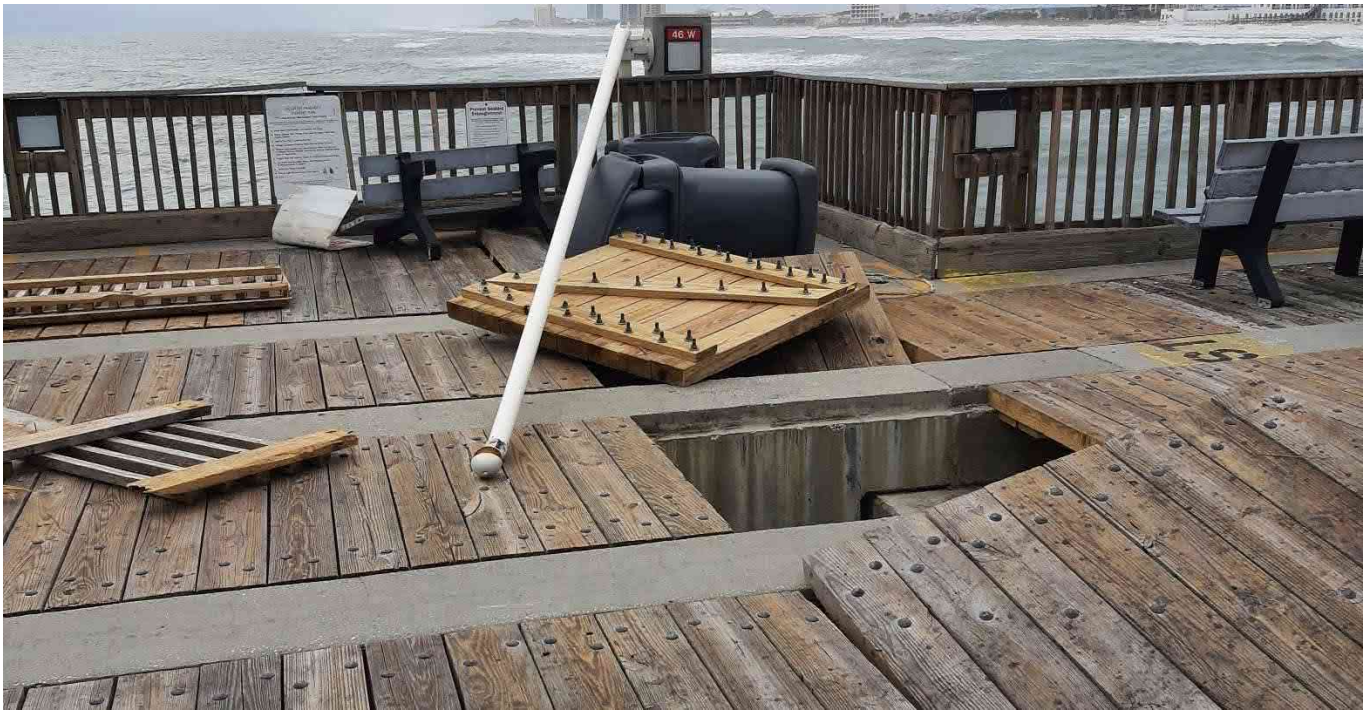

Figure 3 – Timber Deck Blowout Panels adjacent to Bent 46.

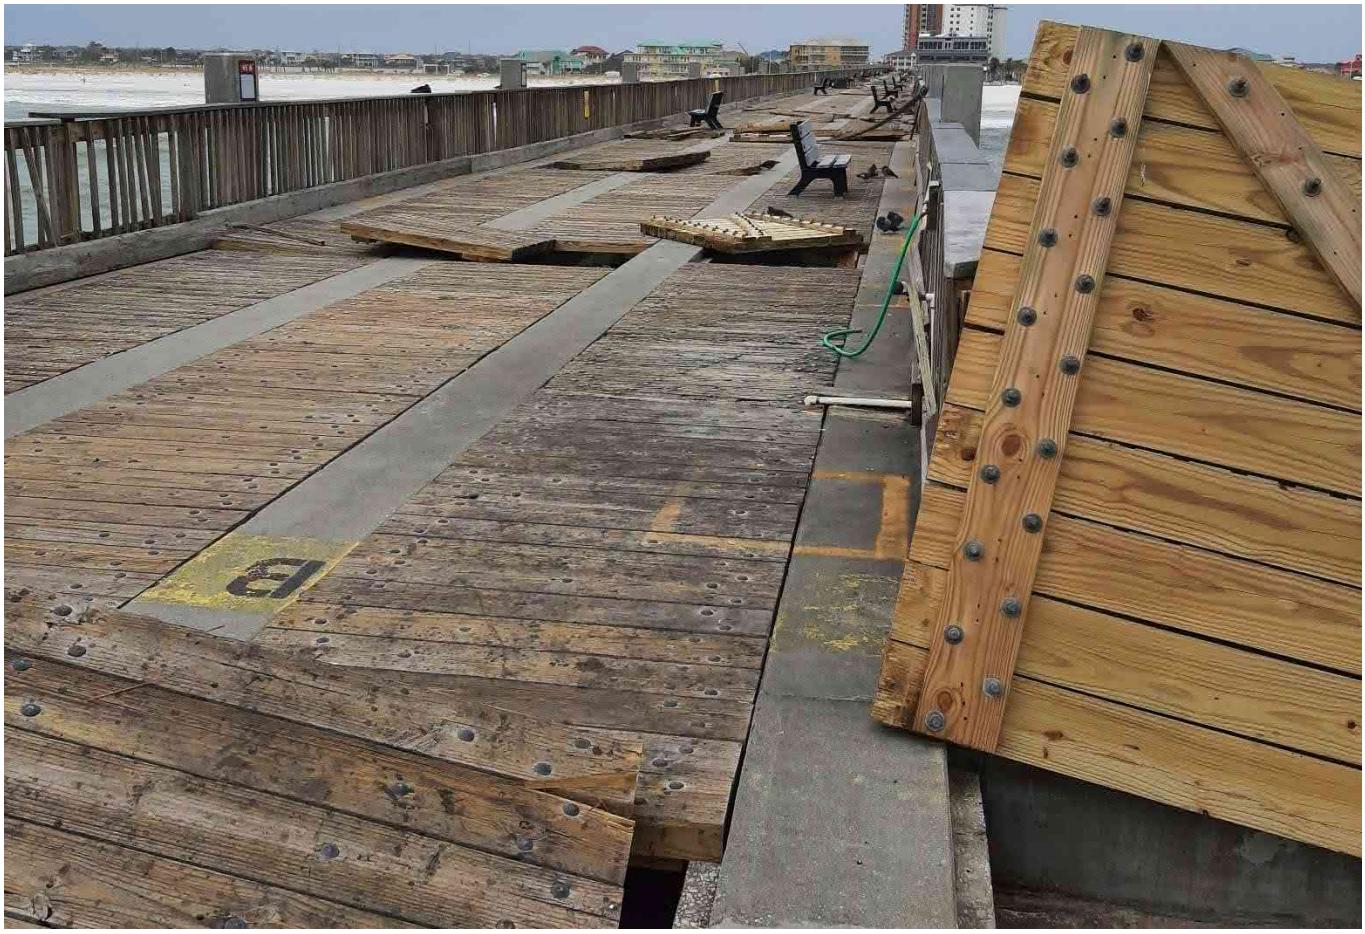

Figure 4 – Timber Deck Blowout Panels typical spans.

Figure 5 – Timber Deck Blowout Panel Dip > 0.5”

Figure 6 – Timber Deck Blowout Panel Gap > 0.5”

Assessing the extent of deck damage caused by the hurricane is difficult because there is considerable previous deck degradation. To quantify the hurricane deck damage, the number of panels blown-out was identified by photos and is listed in Table 1. Escambia County replaced the blown-out panels to provide a safer walking surface for inspections, but full replacement repairs as described above were not performed. In addition to the timber deck panel damage, two benches were damaged and will require repairs prior to placing into service. Note that timber deck damage can occur from lateral and uplift loads during a hurricane without dislodging the panels and all panels may have been shifted during Hurricane Sally. Refer to the Photo Log in Appendix A for documentation of the timber deck condition along the full length of the pier.

Pedestrian Railing Damage:

Wind and waves from Hurricane Sally severely damaged the pedestrian railing along the full length of the pier. Figure 7 shows a typical section of railing which has been completely blown out with only the posts remaining. Remaining posts have been loosened and the timber surface has been damaged where attachments have been ripped away. Also shown in Figure 7 is the damage to a water line and the pier lighting system which included railing lights at mid-span. Where sections of railing remain standing as shown in Figure 8, the railing is loose with timber members damaged and splitting. Typical damaged timber members are shown more closely in Figure 9 where the wood has split. These damaged members cannot be brought back to a condition that meets the building code strength requirements without using epoxy repairs which exceed the cost of the timber. Because it is not economically feasible to salvage the remaining pedestrian railing, the entire railing must be replaced to restore the structure to its pre-storm condition. Replacement of the railing will also require replacement of the attached utilities including electrical, lighting, and water as well as the signage located along the full length of the pier. A damaged viewing telescope was also attached to the railing. The flagpole located at Bent 46 was broken during the storm as shown in Figure 10. The storm also destroyed the entrance gate at Bent 7. Refer to the Photo Log in Appendix A for full documentation of the damage.

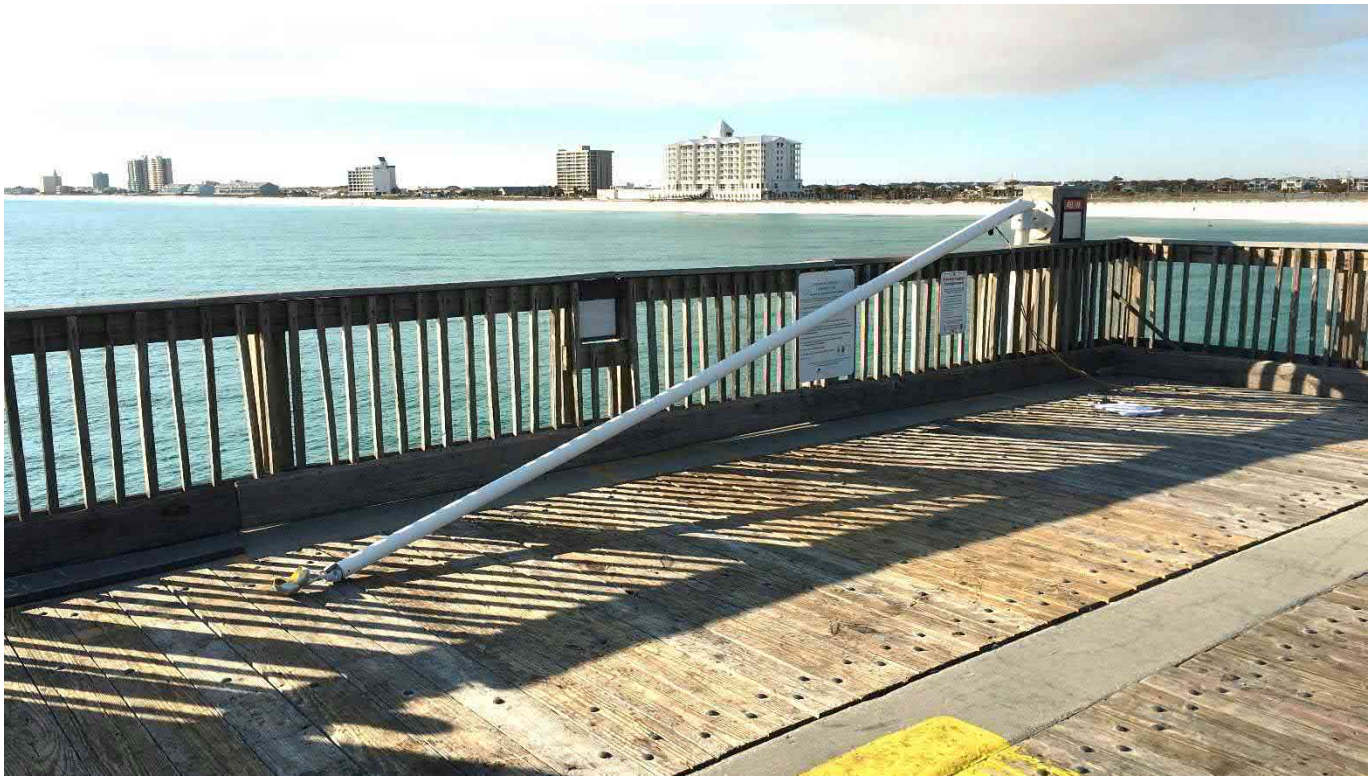

Figure 10 – Broken Flagpole

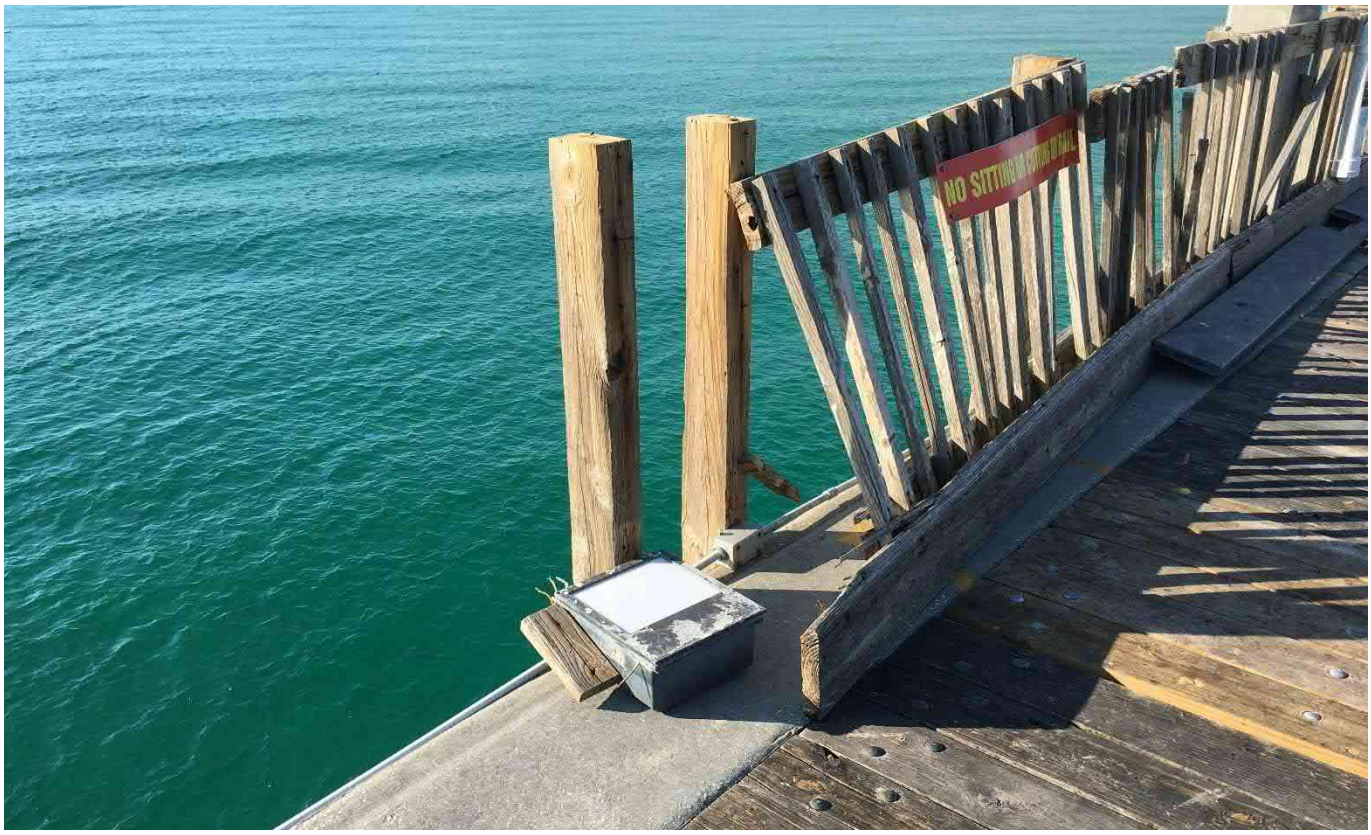

Figure 11 – Damaged Light Fixture

Concrete Damage:

Hurricane Sally likely damaged concrete members through direct water forces, debris impacts, and the movement of the pier under lateral loads. Lateral loading has cracked several light columns as shown in Figure 12 and the cracks must be sealed to prevent continued deterioration.

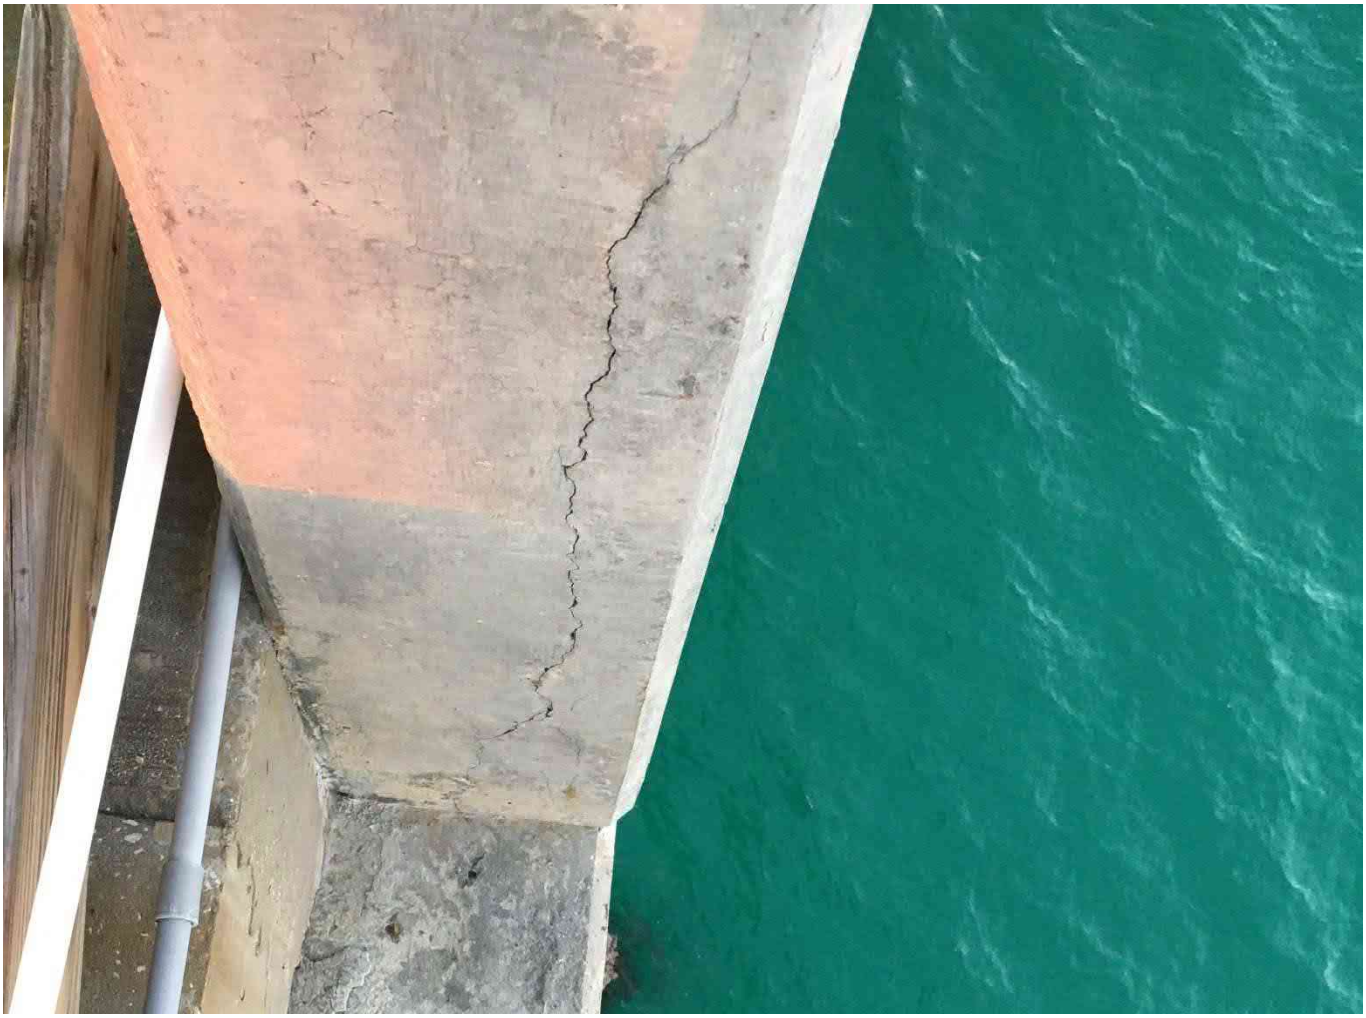

Figure 12 – Typical Light Column Cracking

Wave loading produced longitudinal loads which are transmitted along the full length of the pier. These longitudinal forces resulted in compression in the closure pours between beam ends which produced cracks and spalls in several locations. Cracks in closure pours between concrete sections which are still sound and not loose can be repaired by sealing. Large cracks with loose concrete should be treated and repaired as a concrete spall. The previously repaired closure pour shown in Figure 13 was likely cracked during the hurricane. This longitudinal loading has also caused cracking and spalls in the coped beam ends connected by the closure pours.

Figure 13 – Typical Closure Pour Cracks and Spalls

Figure 14 – Typical Beam End Cracking and Spall

The concrete beams have deterioration in the form of end cracking and spalls, longitudinal bottom flange cracking, and impact spalls along the top flange. Wave impact forces contributes to the beam end cracking and spalls as shown in Figure 14. Longitudinal cracking along the beam length of the beams was not greatly affected by the hurricane but is a problem that must be addressed to prevent future problems. The top flanges of several beams have spalls, as shown in Figure 15, likely from impacts with timber blowout panels during the storm event.

Figure 15 – Typical Beam Top Flange Spall

Hurricane Sally likely caused damage to the concrete pile caps in the form of spalls and cracking. Cracking could occur from the moments produced at the pile tops from wave action lateral loads. These moments can cause small cracks which extend along the pile cap face and spalls which occur at the bottom of the pile cap around the pile. Spalling around the piles due to lateral loading is shown in Figure 16. Pile caps may also be damaged by impact from floating debris during a storm event. These impacts can cause spalls such as that shown in Figure 17.

Figure 16 – Pile Cap Spalls around Piles from Lateral Loading

Figure 17 – Pile Cap Spall from Impact

The concrete piles have also been damaged from wave action and direct impact from floating debris. The longer piles have a series of filled holes which may be part of a splicing system. The holes are indicated as spalls in this report because they represent the same type of damage that spalls present. Previous repairs to fill these spalls have been damaged from wave forces which removed portion of the fill as shown in Figure 18. These spalls must be repaired again along with the repair of new spalls to provide proper protection against corrosion. Refer to the Photo Log in Appendix A for photos of all identified damage. A list of identified concrete spall damage for the pier elements is provided in Table 2 and cracking damage is shown in Table 3.

Pensacola Beach Gulf Pier Information and Details Review

The Pensacola Beach Gulf Pier, also known as the Casino Beach Fishing Pier, is located at 30.3313°N, 87.1428°W extending out from Santa Rosa Island into the Gulf of Mexico. The new pier constructed in 2001 replaced a wooden pier that was destroyed by Hurricane Opal in 1995.

The pier is 1,471' long including the concrete ramp at the base of the pier. The typical width is 20'-0" between the railing and 22'-0" out to out of the concrete light columns. An enlarged section that is 66'-0" long x 42'-0" wide out to out is located at the pier end. At the end the pier deck is 26' +/- above the water and the water depth is 20' +/-. The pier has 47 spans of 30' using prestressed concrete beams supported by concrete pile caps and prestressed concrete piles. The beams are designed as simple span. The deck is composed of timber blowout panels spanning between the concrete beam top flanges.

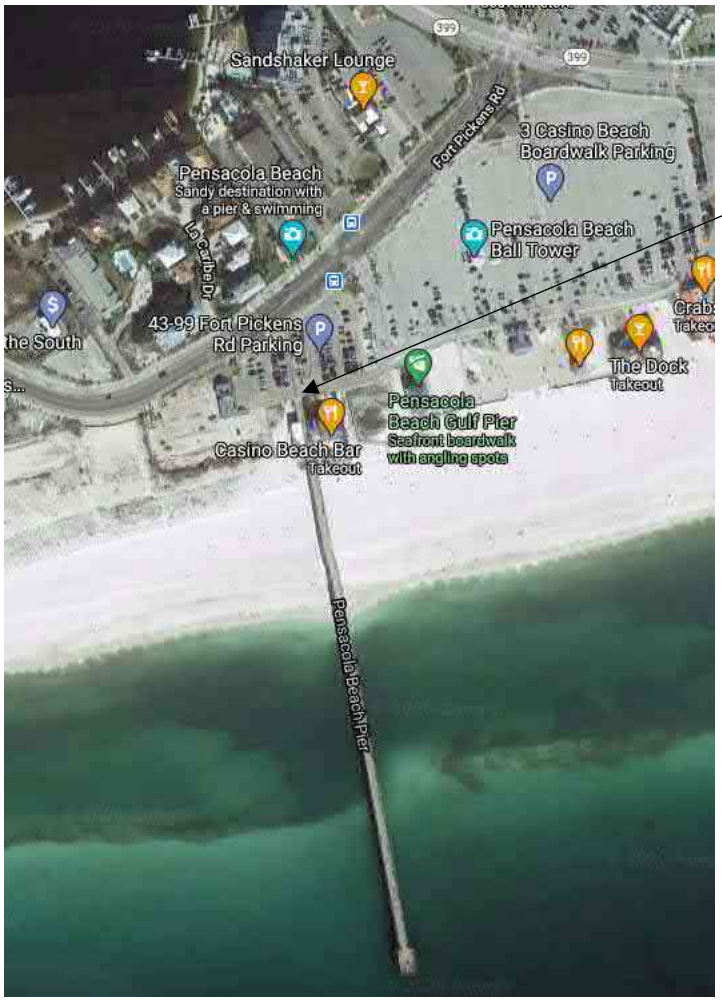

Figure 19 – Pensacola Beach Gulf Pier Location

Pier plans were not made available to Mott MacDonald for this report. The pier performed as designed during the storm with timber panels blowing out to reduce hydraulic forces on the structure. The pier appears to meet current Escambia County standards and desired details with the following exceptions:

1. The pier railing is a constant 42” height which meets the requirements of the current International Building Code (IBC). Escambia County now follows the Americans with Disabilities Act Accessibility Guidelines (ADAAG) which requires that at least 25 percent of the rails be 34” or less in height and that these lower rail sections be positioned in a variety of places on the pier. Note that the ADAAG does not require lower rail sections if the rail is designed to meet all the requirements of the IBC and the local building code requires compliance with the IBC.
2. Timber has proved to require frequent maintenance for both the railing and the decking. In addition, the timber deck blowout panels are difficult to keep in compliance with ADA requirements. Alternate composite materials are desired to replace timber if costs are within required budgets.
3. If timber is used for the railing, revise the design to replace the 2”x2” pickets with a different type of rail panel.
4. Investigate increasing reinforcement in the closure pours with repairs to enable them to transfer higher longitudinal forces without cracks or spalls.
5. The prestressed beams show signs of longitudinal cracking along with end cracking and spalls. Repair and maintenance of these beams may require the addition of cathodic protection to prevent future premature loss of structural capacity through delamination and spalling along the length of the strands. Beam end repairs must eliminate future corrosion and be able to withstand wave impact forces.

Figure 20 – Pensacola Beach Gulf Pier Aerial Photo
(photo from visitpensacolabeach.com)

Recommendations

Rapid repair of the pier damage from Hurricane Sally is recommended to prevent further chloride contamination through cracks and spalls. The repairs needed to restore the Pensacola Beach Gulf Pier to its pre-storm condition include:

1. Replace all pedestrian railing. The new railing should meet ADAAG guidelines.
2. Replace the missing signage, fishing line receptacles, and viewing telescope attached to railing.
3. Replace the electrical wiring and all pier lights with equivalent turtle friendly led fixtures.
4. Replace the water line.
5. Replace the damaged timber deck sections and adjust the blowout panel spacing to meet gap and dip limits of the ADA Section 303 guidelines.
6. Repair and attach the damaged benches.
7. Replace the flagpole.
8. Replace the entrance gate.
9. Repair concrete spall damage and seal concrete cracks in accordance with current FDOT Specifications for Road and Bridge Construction.

In addition to the repairs to damage caused by Hurricane Sally, it is recommended that all prestressed beams be rehabilitated to address end cracking, delamination, and longitudinal cracking which is prevalent throughout the structure. The addition of an active cathodic protection system to arrest active corrosion is recommended for all beams.

Opinion of Probable Construction Cost

The opinion of probable construction cost for the repair of the damage caused by Hurricane Sally is $1.98 million (see Table 4). The item unit costs were derived from several sources as detailed in the notes to Table 4. The inspection performed to identify and quantify the damage was limited in scope and it is anticipated that additional damage will be discovered during the repair project. The construction cost shown includes a 10% contingency for additional damage that will be found during the repair project. The Opinion of Probable Cost considers a standard design – bid – build delivery method. Engineering fees were determined from FEMA's Public Assistance Cost Estimating Tool for Engineering and Design Services. Fees for CEI are based on recent history of similar projects. Mott MacDonald does not guarantee that proposals, bids, or actual costs will not vary from the opinion of probable costs shown. Mott MacDonald does not control the cost of labor, materials, equipment, or services furnished by others, methods of determining prices, or competitive bidding or market conditions. Therefore, any opinions rendered as to costs, including but not limited to opinions as to the costs of construction and materials, have been based on Mott MacDonald's experience and represent the judgment of experienced and qualified professionals, familiar with the industry. In addition, some work included in the opinion of probable costs and schedule may include material or products from areas impacted by

the coronavirus, COVID-19 virus or other disasters. In addition, actions by Governments or Local Authorities resulting in labor disruptions to reduce the effects of a pandemic may occur while this project is under construction. The opinion of probable costs and schedule do not account for and specifically excludes any cost increases, disruptions or delays to the procurement or supply of such materials, or work disruptions caused by the current coronavirus or COVID-19 outbreak or other future disaster events.
